L-10  Relationship between skin surface hydration and subjective skin condition and menstrual cycle phase
Kazanori SHIMAGAMI, Hisako TAKEUCHI and Shinobu MIURA
1) Beauty Culture Laboratory, Kameo, LTD 2) Kameo Foods, LTD.  
The subjects were 27 healthy women from twenties to forties. This investigation  
was executed for 70 days. Each subject measured the basal body temperature, a hornyness moisture content of the cheek and the arm, a room temperature and relative humidity, and checked the subjective skin conditions by five stages oneself every day. Each mean value in the three menstrual cycle phases was compared. The change in the hornyness moisture content concerning to the menstrual cycle was recognized in the subjects of about 30%. The decreasing tendency of the hornyness moisture content was admitted in the luteal phase at the cheek and in the menstrual phase at the forearm. The subjects who felt that some skin conditions of the face changed according to the menstrual cycle were minority. The symptoms which worsened at the menstrual period were dullness, dark circles, complexion, dryness and acne, and which worsened at the luteal phase were acne and skin color brightness. As for putting the skin, the rising tendency was felt in the follicular phase.

L-11  Effect of Task of Short-term Memory on Elderly People's Brain Wave
Masako SATO, Yaka HOSONO, Koraku YAMASHITA and Tamon MIYAMON
Faculty of Human Life Science, Osaka City University
The effect of short-term memory task on brain waves (EEG) has been studied. 
Three healthy subjects, 58.7 year-old on average, and a 60 year-old subject Y.M. 
with a cerebral embolism in his right frontal and temporal lobes were examined. 
The subjects were each asked to memorize 6 cards of different colors and patterns 
for 20 sec., and after 60 sec. of retention, to recognize the 6 cards from among 36. 
The EEG of the subject at 6 points was detected. β/α (%) was analyzed during 
the scheduling of the task, the rest before the task, the memorizing, retention and 
recognition respectively. The correct answer (%) of recognized cards on 
Y.M. was not found difference relative to that of the healthy subjects in 
spite of the significant difference of the β/α (%) caused by cerebral 
embolism.

L-12  Change of Skin Properties with Aging
Sacko MICHE, Miwa NAMURA, Akiko MAEDA, 
Kazuhiko YAMASAKI and Sachiko IIZUKA
Jissen Women's University
The skin properties were observed from view points of aging 
effect and sex difference. The subjects were divided into 3 
groups, namely, YG (20's, α21, β21), MG (40's, α16, β16) 
and SG (60's, α14, β16). The measurement points were 12 
(3 exposed areas, 9 non-exposed areas) in the whole body, and 
measurement items were 9. The climatic chamber was 
controlled at 25 °C 60%RH (in YG, MG) and 28 °C 60%RH 
in SG). In all items the aging effects were seen, especially 
skin color, pliability and subcutaneous fat showed the 
significant changes. Hue shifted by +1.8 for male and +2.6 for 
female in YR area. Chroma shifted by -1.1 for male and +1.3 for 
female. The pliability of SG increased 59% (α2) and 216% 
(β1) than YG or MG. The subcutaneous fat thickness showed 
the most notable sex difference in MG.

L-13  Age-Related-Pattern of Body Composition for Japanese 288 Men and 552 Women
Yasukita TAHARA, Norikitsunawake, Satoshi 
MURAKI, Kouchi YUKAWA and Kazuhiko MOJI
1) Faculty of Education, Nagasaki University 2) Siebold 
University of Nagasaki 3) JHC Nagasaki University 4) School of 
Allied Medical Science Nagasaki University
Body composition was measured for Japanese 288 men and 552 
women, age range of 18-60 yrs. Body density was assessed by 
densitometry and percent body fat (%Fat), fat mass and fat free 
mass were calculated according to Brozek. BMI and skinfold 
thicknesses were also obtained. Following results were obtained.
1) Means of body weight, BMI, skinfolds increased according 
to aging. 2) %Fat showed 14.7% at 18-20yr., 18.7% at 37.5-40yr., 
and 24.3% at 50-55yr. in men. 22.4% at 18-20yr., 24.4% 
at 37.5-40 yr., and 33.4% at 50-55yr in women. 3) Fat mass 
increased from 25yr in men and from 35yr in women 4) FFM 
gradually decreased with age increment, remarkably from 50 
to 55 in men and women.

L-14  The effects of the Two Different Kinds of Pajamas Materials on Thermoregulatory Responses during Nocturnal Sleep
Maki SATO, Tomoko WAKAMURA and Hiromi TOKURA
Department of Environmental Health, Nara Women's University
The study aimed at knowing the effects of the two different kinds of 
Pajamas materials (blend of 80% cotton and 20% linon referred to C1, 
100% cotton referred to C) on thermoregulatory responses during 
night sleep. The experiments were performed at 30°C and 60%RH. 
with 8 female years adults as participants. The results were summarized 
as follows: 1) Rectal temperature was significantly kept lower in C. 2) 
Delta leg skin temperature was significantly greater in C1 during first 3 
hours after retirement. 3) The clothing microclimate temperature 
measured between frontal trunk and pajamas tended to be higher in C1. 
4) Subjective rating to the two different kinds of pajamas materials did not 
differ. The results were discussed in terms of thermal physiology 
and clothing sciences.

L-15  Effects of Skin Pressure Exerted by a Body Compensatory Brassiere on the Amount of Feeces
Nori KIKUFUJI and Hiromi TOKURA
1) Department of Living Sciences, Kyoto Bunkyo Junior College, Uji 611-0041, 2) Department of Environmental Health, Nara Women's University, Nara 630-8506
The present experiment aimed at knowing the effects of skin 
pressure produced by a body compensatory brassiere on defecation 
activity. Seven healthy women, aged 11-41 yrs, served as 
participants, being free of medication and constipation. 
The experiment lasted 3 weeks. The participants did not wear the body 
compensatory brassiere for the first week, wore it during waking 
hours for the second week, and again did not wear it for the third 
week. Whenever they desired to defecate, they did so and then 
measured the amount of feeces. Eating times, daily amounts of food 
and drink, their menstrum, work intensity and its duration, retining 
and rising times were controlled to be as similar as possible from day to day. 
The main finding was that the amount of feeces was significantly 
smaller during the second week than the first and third week . 
We discussed these facts in terms of the suppression of the 
parasympathetic nervous system and intestine motility, and the 
delayed transit time in the large intestine.
