An advanced preparation method was carried out to obtain a magnetized cylindrical micro rotor fabricated from directly consolidated isotropic α-Fe/Pr$_2$Fe$_{14}$B nanocomposite thick-films with self-bonding layer. A magnetic torque of the above film with the remanence value of 0.97 T, the coercivity value of 650 kA/m, and the (BH)$_{\text{max}}$ value of 142 kJ/m$^3$ was investigated under different field strengths. Namely, magnetic torque of the above-mentioned rotor with a single pole pair increased by 117%, compared with that of Fe$_3$B/Nd$_2$Fe$_{14}$B films with the remanence value of 1.1 T, the coercivity value of 334 kA/m, and the (BH)$_{\text{max}}$ value of 95 kJ/m$^3$. It was found that the use of α-Fe/Pr$_2$Fe$_{14}$B films is effective in obtaining a multipolarly magnetized micro rotor with highly dense torque as well as magnetic stability.

I. INTRODUCTION

A micro cylindrical magnets rotor with high permeance coefficient and efficient magnetic properties is required for the highly dense torque in a micro motor for practicable applications.¹ Recently, isotropic Fe$_3$B/R$_2$Fe$_{14}$B micro cylindrical magnets such as 1.5 mm or less in outer diameter were fabricated by melt-injecting into a copper mold.² The obtained magnetic properties, however, were lower than that of melt-spinning method, that the remanence value of less than 0.66 T and the (BH)$_{\text{max}}$ value of less than 69 kJ/m$^3$, respectively. We have already estimated that the magnetic torque of a laminated isotropic Fe$_3$B/R$_2$Fe$_{14}$B film prepared from melt-spinning method with double pole pairs is much larger than that of an anisotropic bulk magnet with a single pole pair.³ We also have developed a small bonded magnet rotor with a relative density of 80% prepared from isotropic α-Fe/Pr$_2$Fe$_{14}$B flakes. It was found that the magnet torque of a small motor using the bonded magnet increased by 114% compared with that of a conventional magnet rotor prepared from Nd$_3$Fe$_{14}$B flakes.⁴,⁵

In this contribution, α-Fe/Pr$_2$Fe$_{14}$B and Fe$_3$B/Nd$_3$Fe$_{14}$B nanocomposite films, respectively, were prepared from melt-spinning method and an investigation on the magnetic torque of each film was evaluated after pulsed magnetization of 4 MA/m to the in-plane direction. It was clarified that an enhancement in the magnetic torque of an α-Fe/Pr$_2$Fe$_{14}$B film with a single pole pair exceeds 117% compared to that of a Fe$_3$B/Nd$_3$Fe$_{14}$B one. We found that an α-Fe/Pr$_2$Fe$_{14}$B nanocomposite film is suitable for highly dense magnetic torque and also magnetic stability.

II. EXPERIMENTAL PROCEDURES

In this section, the detailed preparation processes of two kinds of nanocrystalline films, a directly consolidated film and a bonded magnet, respectively, were described (see Fig. 1).

Pr$_5$Fe$_{77}$Co$_9$B$_7$Nb$_1$V$_1$ and Nd$_{4.5}$Fe$_{70}$Co$_5$B$_{18.5}$Cr$_2$ molten alloys, respectively, were melt spun into an as-cast ribbon with approximately 30 and 45 μm in thickness and 2 mm in average width using a Cu wheel with an outer-diameter of 200 mm in Ar atmosphere at the pressure of 50 kPa. In the melt-spinning process, the ejection pressure of 5 kPa by Ar gas, the orifice of 0.7 mm in the quartz crucible, and the wheel speed of 30 m/s, respectively, were used. The as-cast ribbons were cut to 50 mm or less in length and crystallized at the elevated temperature of 650 and 680 °C for 0 and 10

min with heating rate of 300 and 200 °C/min, respectively. After cooling them to room temperature, Nb-V-Co-doped \( \alpha \)-Fe/Pr\(_2\)Fe\(_{14}\)B and Cr-Co-doped Fe\(_3\)B/Nd\(_2\)Fe\(_{14}\)B ones were coated with approximately 5-\( \mu \)m-thick or less self-bonding layers.

Each film was pierced into a disk shape under a pressure up to 50 kN. The intended dimensions are 1.6 mm in outer diameter. In addition, the directly consolidated film was prepared into several specific lengths such as approximately 0.5–2.0 in L/D ratio (L: length, D: diameter) in the punching. Namely, the directly consolidated film was solidified under a pressure of 50 MPa at the temperature of 180 °C for 5 min. A rigid consolidated film obtained through the cross-linking was magnetized to an in-plane direction under the pulsed magnetic field of 4 MA/m.

We also prepared a consolidated flake (bonded magnets) by using the above-mentioned film. The particle size of the compound was adjusted to 350 \( \mu \)m or less by crushing and sieving-classification. The obtained compound was compacted into a specific shape with 1.6 mm in outer diameter under a pressure of 1 GPa at 180 °C. Through the compaction, a rigid sample for comparison could be obtained by cured of self-bonding material.

### III. RESULTS AND DISCUSSION

An investigation on x-ray diffraction pattern, magnetic properties, and magnetic torque was carried out. Each magnetic torque in rotating field range from 4 to 400 kA/m was measured with a magnetic torque meter.

The amorphous state of as-spun ribbons as a homogeneous precursor is important for crystallographically coherent formation of nanocrystalline hard magnetic phases and soft magnetic phases simultaneously, which insures a strong exchange coupling between the two phases.\(^6\) In the experiment, we confirmed that an \( \alpha \)-Fe/Pr\(_2\)Fe\(_{14}\)B film and also a Fe\(_3\)B/Nd\(_2\)Fe\(_{14}\)B one consists of Fe\(_3\)B, R\(_2\)Fe\(_{14}\)B and \( \alpha \)-Fe phases as seen in Fig. 2. We, further, prepared film specimens with approximately 2 mm\(^2\) in order to evaluate magnetic properties to an in-plane direction by using a VSM after pulse-magnetization at 4 MA/m, and we confirmed that they had typical magnetic properties of 0.97 and 1.1 T in remanence, 650 and 334 kA/m in coercivity, 142 and 95 kJ/m\(^3\) in (BH)\(_{\text{max}}\) respectively, as seen in Fig. 3.

The magnetic torque of an obtained film was examined with a magnetic torque meter because the measured magnetic torque is more applicable than the evaluation on general S-T equipment in the magnetized cylindrical micro rotor with a single pole pair. According to the calculation by a 3D finite element model as seen in Fig. 4, assuming that the outer diameter of the magnetized film is constant, the volume magnetic torque with the thickness range of 10–300 \( \mu \)m hardly changes; on the other hand, the volume magnetic one obviously decreases as film thickness exceeded 300 \( \mu \)m or more. The above-mentioned reduction is considered to be attributed to a shape-magnetic-anisotropy deterioration of a film.

Figure 5 shows the volume magnetic torque of an \( \alpha \)-Fe/Pr\(_2\)Fe\(_{14}\)B film with a single pole pair as a function of field strength compared with that of a Fe\(_3\)B/Nd\(_2\)Fe\(_{14}\)B one. As the field range was between 4 and 40 kA/m, good linearity of a torque peak as well as same phases of the torque curves.
In the above field at 8 kA/m, the volume magnetic torque of an α-Fe/Pr$_2$Fe$_{14}$B film was 9.2 μNm/mm$^3$, which was 117% larger than that of a Fe$_3$B/Nd$_2$Fe$_{14}$B one. Although a distortion factor of the magnetic torque curve deteriorated remarkably at a strong magnetic field higher than 80 kA/m, an α-Fe/Pr$_2$Fe$_{14}$B film was relatively smaller deterioration than that of a Fe$_3$B/Nd$_2$Fe$_{14}$B one. It is generally said that the effect of the short-term flux loss, which is attributed to irreversible magnetization reversal at an exposed temperature, is more important than that of the long-term flux loss in magnet torque of cylindrical magnetized micro rotor. In the systematic evaluation on the flux loss in nanocomposite bonded magnets with the various coercivity values, we have already found that short-term as well as long-term flux losses in several nanocomposite bonded magnets were smaller than that of a conventional isotropic Nd$_{10.5}$Fe$_{83.5}$B bonded magnet despite their small coercivity values.

The relationship between distortion factor and coercivity values, we have already found that short-term as well as long-term flux losses in several nanocomposite bonded magnets were smaller than that of a conventional isotropic Nd$_{10.5}$Fe$_{83.5}$B bonded magnet despite their small coercivity values.

The relationship between distortion factor and short-term flux loss, therefore, was investigated in the study. Figure 6(a) shows the relationship between the distortion factor of magnetic torque curves and short-term flux loss as a function of coercivity values. Here, the short-term flux loss values of three consolidated nanocomposite flakes such as Nd$_{10.5}$Fe$_{83.5}$B were also displayed.

The dependency of distortion factor of each film together with short-term flux losses of consolidated flakes on coercivity values showed the same tendency, and both the vertical values drastically increased at coercivity value lower than approximately 600 kA/m. These results suggest that the distortion factor of the magnetic torque curve of each magnetized sample is attributed to a magnetization reversal. Resultantly, an α-Fe/Pr$_2$Fe$_{14}$B film with a highly dense magnet torque as well as a satisfactory magnetic stability for micro cylindrical magnet rotor application could be prepared.

Preparation of a directly consolidated film enabled us to achieve an enhancement in the magnetic torque on the shape magnetic anisotropy and increase relative density compared with that of a consolidated film with same dimension and alloy composition. Table I shows a typical relative density, volume magnetic torque, and dT/dH-gradient of α-Fe/Pr$_2$Fe$_{14}$B-based directly consolidated films and flakes.

In this study, we succeeded in a highly dense torque as well as magnetic stability by taking advantage of a shape-magnetic-anisotropy due to an optimized material form and L/D ratio through the preparation of a directly consolidated film with approximately 1.6 mm in outer diameter comprising isotropic α-Fe/Pr$_2$Fe$_{14}$B nanocomposite thick-films with self-bonding layer.
