Abstract – Anodic reactions are desirable methods from the viewpoint of Green Chemistry, since no toxic oxidants are necessary for the oxidation of organic molecules. This review introduces usefulness of anodic oxidation and successive reaction for selective functionalization of cyclic amine derivatives.

1. INTRODUCTION
It is well-known that anodic oxidation is useful for selective functionalization of N-protected cyclic amine derivatives.1-3 Especially, Shono and Matsumura’s pioneer works enabled Lewis acid mediated Mannich-type reaction between N,O-acetals B prepared by anodic oxidation of amine derivatives A and carbon nucleophiles (Nu−) is one of the powerful methods for synthesis of α-substituted amine derivatives C (Scheme 1).4 In these reactions, N-acyliminium ions D are key intermediates.5 Recently, excellent
methods for oxidation and/or amidoalkylation of carbamates, such as the “cation pool method”, the “cation flow method”, “recyclable solid supported bases”, and “parallel electrosynthesis” were developed.

As shown in Scheme 2, removal of alcohols from N,O-acetals B generated enamine derivatives E which reacted with electrophiles to afford β-substituted enamines F. Anodic oxidation of E in acetic acid gave α,β-diacetoxy-α-substituted amines G which were directly obtained from amines A by anodic oxidation in acetic acid. Lewis acid promoted nucleophilic substitution gave β-acetoxy-α-substituted amines H.

Scheme 1. Anodic α-functionalization of cyclic amine derivatives

Scheme 2. Anodic β-functionalization of cyclic amine derivatives

Anodic oxidation of A or E in the presence of halogen ion (X⁻) afforded β-halogeno-α-methoxylated amines I. Dehydrohalogenation of I effectively afforded α-methoxy-β,γ-unsaturated amines J which were not only synthetic precursors for 1,2-dihydropyridines K but also γ-substituted enamines L. Also, Lewis acid promoted nucleophilic substitution of I afforded β-halogeno-α-substituted amines M. When Nu was the active methylene groups, base catalyzed migration of the methylene groups occurred to give β-substituted enamines N (Nu=active methylene). Similarly, aryl groups of β-halogeno-α-arylated
amines M (Nu=Ar) were easily shifted to the β-position by Ag⁺ (Scheme 3).¹⁶

This review majorly introduces recent progress on anodic method for selective functionalization of cyclic amine derivatives developed by our group.

Scheme 3. Further functionalization of β-halogeno-α-methoxylated amines I

2. ANODIC OXIDATION OF CYCLIC AMINE DERIVATIVES
2-1. Regioselectivity
Usually, direct electrochemical oxidation of N-acylated cyclic amine derivatives A as shown in Scheme 1 occurred at the less substituted carbon because of steric factor between substrate and anode, while some methods for electrochemical oxidation at the more substituted carbon were developed. Namely, electrochemical oxidation of bicyclic amine prepared from (∆S)-prolinol and trifluoroacetalddehyde proceeded to afford enantiomerically pure methoxylated compound in excellent regioselectivity. This product was easily transformed into (∆S)-α-allylprolinol (Scheme 4).¹⁷ Also, N-cyano cyclic amines were regioselectively methoxylated at the more substituted carbon by electrochemical oxidation (Scheme 5).¹⁸ Such unusual selectivity might be explained by stability of the corresponding intermediary iminium ions.

Scheme 4. Anodic synthesis of (∆S)-α-allylprolinol
On the other hand, Dhimane reported that anodic oxidation of bicyclic carbamate afforded a mixture of regio isomers (Eq. 1).\(^{19}\)

\end{align*}
\]

57\% yield 1 : 3

2-2. Diastereoselectivity

A highly efficient direct cyanation of \(N\)-protected cyclic amines by anodic oxidation was developed.\(^ {20}\) The regioselectivity was similar to the anodic methoxylation of \(N\)-protected cyclic amines. This anodic cyanation of L-proline derivative proceeded to afford 5-\(cis\) substituted product in excellent diastereoselectivity (Scheme 6).

Also, under acidic conditions, electrochemical \(\alpha\)-cyanation of cyclic amines proceeded selectively (Eq. 2).\(^ {21}\)

\begin{align*}
\text{Eq. 2} & \quad \text{MeO} \\
& \quad \text{MeO} \\
& \quad \text{Me} \\
& \quad \text{Me} \\
\end{align*}
\]

92\% yield cis/trans = 100 : 0

Recently, Pilli and Santos published their work\(^ {22}\) on electrochemical cyanation using two methods. In the case of the “cation pool” method\(^ {23}\) using a combination of TMSCN and TMSOTf, they achieved
high yield and enantioselectivity, on the other hand use of the “non-cation pool” electrochemical method using TMSCN gave very low yield and required low temperatures (−78 °C). In addition Tajima has published their work on electrochemical cyanation based on the concept of site isolation.24 

Since N-protected enamines are representative electron-rich olefins, they are relatively oxidizable. Direct electrochemical oxidation of 6-acetoxymethyl-2,3-didehydropiperidine derivative afforded 3,6-trans isomer, while indirect one gave 3,6-cis isomer in high diastereoselectivity. On the other hand, indirect method using I− as a mediator proceeded via inversion of the stereochemistry (Scheme 7).25

![Scheme 7. Direct and indirect electrochemical oxidation of enamine derivatives](image)

Although iodohydroxylation afforded 3-trans-iodinated intermediate, successive epoxidation by electrogenerated base (EGB) occurred with the inversion of the stereochemistry at the 3-position (Scheme 8).

On the other hand, α,β-dihydroxylated cyclic amine derivatives were somewhat unstable to be easily transformed into ring opened hydroxyketones which were changed to imines by acid in the presence of MgSO4. These imines were precursors for α,α-disubstituted cyclic amines (Scheme 9).26

![Scheme 8. Stereochemical course for indirect electrochemical oxidation of enamine](image)
Scheme 9. Ring contraction of α,β-unsaturated cyclic amine derivatives

The direct oxidation in acetic acid was applicable to α-methoxy-β,γ-didehydropiperidine derivatives to afford optically active imino-sugar precursors. In these reactions, γ-acetoxy-α,β-didehydropiperidine derivatives generated by acetic acid were anodically oxidized (Scheme 10).²⁷

Scheme 10. Diastereoselective preparation of imino-sugar precursors

2.3. Enantioselectivity
A decarboxylative methoxylation of an N-acylated amino acid (non-Kolbe reaction) leads to N-acyl-iminium ion intermediate.²⁸ Although transformation of optically active α-amino acid into active intermediates without any loss of optical purity is useful for synthesis of optically active nitrogen-containing compounds, intermediary iminium ion which is a typical sp² cation, might lose the original chirality to afford racemic product (Scheme 11).

Scheme 11. Usual anodic decarboxylative substitution of N-acyl α-amino acids
However, when N-o-phenylbenzoylated oxazoline and thiazoline derivatives were electrochemically oxidized, the memory of chirality via carbenium ion chemistry occurred to afford optically active products (80% and 91% enantiomeric excess (ee), respectively) in Eq. 3.\textsuperscript{29,30}

\[\text{MeO}^-_{\text{Me}} - 2e^{-} \rightarrow \text{MeOH}^{-30 \degree C}\]

Scheme 12 shows plausible stereochemical course for the memory of chirality.\textsuperscript{31} The initial step involves the oxidative decarboxylation of amino acid to form the iminium ion, which can be attacked by nucleophiles (MeO\textsuperscript{-}) from the \textit{syn} or the \textit{anti} side. The observed 85% ee could be attributed to the presence of the bulky o-phenyl group beneath the carboxylic group and the fixation of the conformation of amino acid and of iminium ion intermediate at low temperature. The restricted rotation could have favored the formation of a chiral iminium ion with the conformation of an o-phenyl group similar to that of the amino acid. The bulky o-phenyl group could have precluded an effective approach from the anti side, and hence the nucleophilic attack was predominantly from the less hindered \textit{syn} side resulting in 4\textit{R}-isomer.

Anodic oxidation of N-acyl-\textit{β}-amino alcohols smoothly cleaves the carbon-carbon bond to afford \textit{N,O}-acetals.\textsuperscript{32} The memory of chirality was observed in the anodic substitution of optically active \textit{β}-amino alcohol derivatives (Eq. 4).\textsuperscript{33}
On the other hand, indirect electrochemical oxidation in the presence of chiral copper catalyst transformed *racemic* *N*-protected aminoalcohols into optically active amino esters in kinetic resolution manner (Scheme 13).\(^{34}\) Similar kinetic resolution of *racemic* *N*-protected aminoalcohols proceeded to afford optically active amino esters. In this reaction, chelation of amino alcohol or amino aldehyde with Lewis acid activate their hydroxyl or formyl group to form alkoxide ion which is easily oxidizable compared with the original amino alcohol or aldehyde (Scheme 14).\(^{35}\)

- **Scheme 14.** Reaction mechanism for enantioselective oxidation of amino alcohol or aldehyde
2-4. Anodic cyclization for preparation of cyclic amine derivatives

Shono and Matsumura reported that indirect electrochemical intramolecular carbon-nitrogen bond forming reaction of \(N\)-tosylaminoalkylmalonates smoothly proceeded to afford cyclic amine derivatives (Scheme 15).$^{36}$

\[

Scheme 16. Coupling of nitrogen and alkene

On the other hand, important intermediate for preparation of carbapenam antibiotics was synthesized by electrochemical intramolecular carbon-carbon bond forming reaction (Scheme 17).$^{38}$ In this cyclization, \((R)\)-phenylethyl group works as a good chiral auxiliary.
3. SYNTHETIC APPLICATION OF ANODIC PRODUCT

3-1. Nucleophilic substitution

Lewis acid mediated nucleophilic substitution of N,O-acetals was accomplished under solvent-free condition to afford the substituted products in high yields similar to the yields in dichloromethylene (Eq. 5). Also, indium-mediated benzylation and allylation of α-methoxy-β,γ-unsaturated amines were accelerated in water compared with in tetrahydrofuran (Eq. 6). Nucleophilic substitution of N,O-acetals with unmodified ketones was promoted by a combination of TiCl₄ and PhSiCl₃ (Eq. 7). These reactions might be desirable from the viewpoint of Green Chemistry.

\end{align*}
\]

3-2. Diastereoselective nucleophilic substitution

Since nucleophilic substitution of α,β-diacetate G majorly afforded trans-β-acetoxy-α-substituted cyclic amines H in Scheme 2, it was somewhat difficult to obtain cis-β-hydroxy-α-substituted one in high diastereoselectivity. Recently, a highly cis-selective synthesis of α,β-disubstituted piperidines has been accomplished through nucleophilic additions to N-acyliminium ions with aryl- and alkenyl boronic acids (Eq. 8).
Diastereoselective nucleophilic substitution of piperidine derivative at the 6-position smoothly proceeded to afford cis-isomer, while control of diastereoselectivity in case of prolinate derivative was difficult. Recently, we found that the N-protecting group affected the diastereoselectivity. That is, N-methoxycarbonylated prolinate mainly gave cis-allylated prolinate (cis/trans = 73/27), while N-benzoylated prolinate preferentially changed into trans-allylated prolinate (cis/trans = 13/87) (Eq. 9).

Arylation of 5-methoxylated L-prolinates showed similar tendency to their allylation (Eq. 10).

This diastereoselective arylation was applicable to preparation of cis-5-arylated N-formyl-L-proline or C2-symmetrical pyrrolidine derivative which worked well as an organic activator in the enantioselective reduction of ketones or imines with Cl₃SiH in high enantioselectivities (Eqs. 11 and 12).
Similar effect of N-protecting group on the diastereoselectivity was observed in the Arbusov reaction of 5-methoxylated L-prolinates with phosphites in the presence of BF₃·OEt₂ (Eq. 13).⁴⁸

Electrochemical oxidation of N-acyl-α-allyl or benzyl amines smoothly cleaved the carbon-carbon bond to afford N,O-acetals. The allyl groups worked as chiral auxiliary to afford optically active quaternary cyclic amino acids (Scheme 18).⁴⁹

Methylphenidate has four stereoisomers since it possesses two asymmetric carbons. Among them, the threo-methylphenidate hydrochloride salt (Ritalin®) has been used mainly for the treatment of attention deficit hyperactivity disorder (ADHD) in children in the USA. Although threo-methylphenidate was administered to patients as the racemic form, the most active enantiomer is the d-threo-isomer. TiCl₄
Mediated nucleophilic substitution of $N,O$-acetal with Evans imide proceeded to afford a precursor for $d$-threo-methylphenidate in highly diastereoselective manner (Eq. 14).\textsuperscript{50}

3-3. Enantioselective nucleophilic substitution

Enantioselective introduction of carbon nucleophiles ($\text{Nu}^-$) onto cyclic $N$-acyliminium ions has attracted much interest because it provides an efficient route for elaboration of optically active piperidine and pyrrolidine derivatives. The reaction of $\alpha$-methoxypyrrolidine with silyl enol ether in the presence of a chiral titanium catalyst to afford substituted product as a mixture of diastereomers in 68\% de with 53\% ee for major diastereomer (Eq. 15).\textsuperscript{51}

\[

\end{align*}
\]

57\% yield
97\% ee
On the other hand, chiral copper ion-catalyzed coupling reaction of $\alpha$-methoxylated $\beta$-ethyl-$\beta,\gamma$-didehydropiperidines with acetoacetate proceeded to afford $\gamma$-substituted piperidines as a mixture of diastereomers in a ratio of 56/44, each of which had moderate optical purity (43-44% ee) (Eq. 18).\textsuperscript{54}

3-4. Electrophilic substitution

Regioselective introduction of various electrophiles (aldehydes, ketones, and imines) into piperidine derivatives at the 4-position was accomplished.\textsuperscript{55} Scheme 19 shows the strategy for generation of nucleophilic species from anodically prepared $N$-protected 2,3-didehydro-4-acetoxypiperidine $P$, followed by generation of $\pi$-allyl palladium $Q$ from $P$ by Pd(OAc)$_2$/PPh$_3$ and then, successive umpolung of $Q$ mediated by Et$_2$Zn.\textsuperscript{56}

The reaction of pipecolinate derivative with acetone proceeded regio- and stereo-selectively to afford $cis$-2,4-disubstituted product in high yield (Eq. 19).
Using chiral phosphine ligand afforded optically active product as a diastereomer mixture in moderate diastereoselectivity and enantioselectivities (Eq. 20).

\[
\begin{align*}

& \quad \text{OAc}
\end{align*}
\]

3-5. Preparation of azabicyclic compounds

Optically active 2,3-methanopipelicolic acid was prepared by procedures shown in Scheme 20 from anodically prepared cis-6-methoxypipecolinate (94% de).\(^{57}\) Firstly, cis-6-methoxypipecolinate was phenylthiolated at the 2-position by the treatment with potassium bis(trimethylsilyl)amide (KHMD) and diphenyldisulfide, successively, and the resulting product was oxidized with \(m\)-CPBA to give 2,3-didehydropipecolinate. The treatment of 2,3-didehydropipecolinate with dimethylsulfoxonium methyldi in DMSO gave 2,3-methano-6-methoxypipecolinate in high deastereoselectivity. The subsequent reductive elimination of its 6-methoxy group was nicely done by adding \(\text{NaBH}_4\) to afford 2,3-methanopipecolinate in 85% ee. Finally, its hydrolysis by trimethylsilyl iodide afforded (2S,3R)-methanopipecolinic acid.

A versatile organocatalyst 2,2,6,6-tetramethylpiperidine-N-oxyl (TEMPO) has been utilized in chemical and electrochemical oxidation of alcohols as a mediator. TEMPO is a stable but sterically hindered radical because of the four methyl groups adjacent to the nitroxyl group. Therefore TEMPO is not suitable for the oxidation of sterically hindered alcohols. In 2006, Iwabuchi reported an excellent oxidation of sterically hindered alcohols using 1-methyl-2-azaadamantane-N-oxyl (1-Me-AZADO), which is one of the sterically less hindered class of nitroxyl radicals (Fig. 1).\(^{62}\) On the other hand, the ability of azabicyclo-N-oxyls for the oxidation was unknown.

\[\text{Figure 1. Structures of some N-oxyls.}\]

Shono and Matsumura developed preparation method for N-methoxycarbonyl-8-azabicyclo[3.2.1]octane
and N-methoxycarbonyl-9-azabicyclo[3.3.1]nonane (Eq. 24). These compounds were transformed into the corresponding N-oxyls and/or N-hydroxyls (Eq. 25).

These N-oxyls and/or N-hydroxyls were applicable to chemical and electrochemical oxidation of sterically hindered alcohols as mediators (Scheme 21).

Similarly, chiral azabicyclo-N-oxys were prepared by utilizing anodic oxidation starting from L-hydroxyproline and D-pipecolinic acid as shown in Schemes 22 and 23.
Scheme 22. Preparation of chiral N-oxyls from L-hydroxyproline

These chiral N-oxyls mediated kinetic resolutions of secondary racemic alcohols in moderate $s$-values (Eq. 26).

**4. CONCLUSION**

This review focused on some subjects on electro-organic synthesis, such as control of chemoselectivity, regioselectivity, diastereoselectivity, enantioselectivity, and their important synthetic applications. These developments for the subjects outlined above, may increase the potential of anodic synthesis. Since anodic reaction usually occurs on surface of electrode, in future, the synthesis in heterogeneous medium might afford different progress from chemical synthesis which is usually in homogeneous medium.

**ACKNOWLEDGEMENT**

I express my heartfelt gratitude to the late Prof. Y. Matsumura for his helpful guidance.
