Abstract
Highly regioselective 5-exo bromolactonizations of stilbene-type carboxylic acids bearing electron-withdrawing substituents were first achieved via the use of chiral bifunctional sulfide catalysts possessing a urea moiety. The chiral phthalide products were obtained in moderate to good enantioselectivities as the results of 5-exo cyclizations.

Key words asymmetric synthesis, lactonization, organocatalysis, regioselectivity, sulfides

Catalytic asymmetric reactions with modularly designed organocatalysts are recognized as one of the most effective methods to produce important chiral molecules in a highly enantioenriched form. Various types of chiral organocatalysts have been designed and applied to highly stereoselective transformations over the past two decades. Among these organocatalysts, chiral amines and phosphines are some of the most widely utilized catalysts in catalytic asymmetric synthesis. By comparison with an exorbitant number of reactions using chiral amine and phosphate catalysts, examples of efficient asymmetric reactions with chiral sulfide catalysts have remained limited and under-developed. In this context, we became interested in the design of effective chiral sulfide catalysts and successfully developed bifunctional catalysts (S)-4 for highly enantioselective bromolactonizations with stilbene-type carboxylic acids 1 (Scheme 1). In previous work, we selectively synthesized 3,4-dihydroisocoumarin products 3 via 6-endo cyclization under optimized reaction conditions with selected substrates, and 5-exo products 2 were not formed. During the course of an extension of the substrate scope for the asymmetric bromolactonization of 1, we found that 5-exo cyclization products 2, which possess a phthalide structure as an important structural motif, could be selectively obtained in a reaction with stilbene-type carboxylic acids 1 bearing electron-withdrawing substituents (Scheme 1). Herein, we report a catalyst-controlled regio- and stereoselective 5-exo bromolactonization of 1 with bifunctional chiral sulfides (S)-4.

Asymmetric bromolactonization of 1a possessing a trifluoromethyl group was selected as a model reaction in an attempt to develop an effective catalyst for 5-exo-selective cyclization. Yeung reported that the 5-exo cyclization product 2a was preferentially obtained in the bromolactonization of 1a with or without catalysts in low to moderate regioselectivities (2a:3a = 2.1–4.1). Our original aim was to improve regioselectivity via the use of bifunctional sulfide catalysts (S)-4 (Table 1). An attempted reaction of 1a with N-bromosuccinimide (NBS) in CH$_2$Cl$_2$ under the influence of a phenylurea-type bifunctional catalyst (S)-4a at 0 °C for 24 h provided bromolactonization product 2a in a good yield with moderate levels of regio- and enantioselectivity (Table 1, entry...
1. Encouraged by this result, a fine-tuning of the urea moiety on catalyst (S)-4 was performed to improve the regioselectivity. Although the introduction of arylurea possessing electron-donating groups on the catalyst (4b) caused a reduction in regioselectivity (Table 1, entry 2), catalysts bearing electron-deficient arylureas (4c and 4d) improved the levels of both regio- and enantioselectivity (Table 1, entries 3 and 4). A higher level of regioselectivity was observed in a reaction with catalyst (S)-4d (Table 1, entry 4). To establish the importance of the urea moiety on catalysts (S)-4, we also examined the reactions with related BINOL-derived catalysts (S)-5a and 5b. Although these catalysts promoted the bromolactonization of 1a, the 5-exo cyclization product was obtained only in low levels of regio- and enantioselectivity (Table 1, entries 5 and 6). Additionally, the reaction without a catalyst slowly proceeded under the reaction conditions with low regioselectivity (Table 1, entry 7). These results clearly suggested that a urea moiety of catalysts (S)-4 was essential to obtaining good levels of regio- and enantioselectivity in the present 5-exo bromolactonization.

We also examined the effect of brominating reagents under the influence of optimized catalyst (S)-4d (Table 2). The levels of regio- and enantioselectivity for product 2a significantly depend on the structure of the brominating reagents. Reactions with brominating reagents possessing 5- and 6-membered ring structures generally gave the target 5-exo cyclization product 2a in good to high levels of regioselectivity with moderate to good levels of enantioselectivity (Table 2, entries 1–4). On the other hand, N-bromoacetamide (NBA) as an acyclic brominating reagent gave product 2a with lower levels of regio- and enantioselectivity (Table 2, entry 5). Interestingly, the 6-endo cyclization product 3a was obtained in good regioselectivity when the reaction was performed with bromine (Br₂) as a brominating reagent, although almost no enantioselectivity was observed (~50:50 er, Table 2, entry 6).

Among these brominating reagents, the highest level of regioselectivity for 2a was observed with dibromoisocyanuric acid (DBI), and the highest levels of enantioselectivity were achieved with NBS and DBI (Table 2, entries 1 and 4).
Scheme 2 Substrate scope. * Enantioselectivities of products 3 were low (lower than 59:41 er).
With the optimal catalyst (S)-4d and reaction conditions in hand, we studied substrate generality for the 5-exo-selective bromolactonization of 1 (Scheme 2). Both NBS and DBI were examined as possible brominating reagents that could provide generality in each substrate. First, we investigated the effect that an electron-withdrawing group (EWG) would exert on an aromatic ring (Ar) at the para-position of 1. The application of stilbene-type carboxylic acids 1 bearing a variety of EWGs produced highly regioselective reactions and products 2a–d in moderate to good levels of enantioselectivity. In general, the reactions with DBI provided higher levels of regioselectivity with slightly lower levels of enantioselectivity than those of the reactions with NBS. The reactions of 1 that possessed EWGs at the meta- and ortho-positions were also examined, and products 2e–g were obtained with high levels of regioselectivity. On the other hand, the reactions with simple substrate 1h (Ar = Ph) without EWG produced bromolactonization products 2h and 3h with low levels of regioselectivity, and 6-endo cyclization product 3h was a major product even under the optimal reaction conditions for 5-exo cyclization. It should be noted that a complete regioselective reaction to produce 3h in a highly enantioselective manner was achieved with catalyst (S)-4a under low reaction temperature conditions. These opposite trends in regioselectivity could be explained by the nature of the substrates (Figure 1). When the reaction was performed with a simple substrate, 1h (Ar = Ph), 6-endo cyclization was favored due to stabilization of the cationic nature on the benzyllic carbon of the phenyl group (A in Figure 1). On the other hand, the introduction of EWG on the aryl moiety (Ar) destabilized the cationic nature on the benzyllic carbon. As a result, 5-exo cyclization was favored slightly more than 6-endo cyclization (B in Figure 1). This trend for the production of 5-exo bromolactonization products 2 was enhanced by the reactions using urea-type bifunctional sulfide catalysts (S)-4, due to the formation of a well-organized intermediate (C in Figure 1). The substituent effects on the other aromatic ring (Y) of 1 were also examined to produce 2i–l (Scheme 2). Even with the introduction of EWGs to another aromatic ring (Y), the reactions proceeded with good levels of regioselectivity to give 2i and 2j. The products 2k and 2l possessed electron-donating groups and were obtained in good levels of regio- and enantioselectivity.

In summary, we successfully achieved hitherto unknown highly regioselective 5-exo bromolactonizations of stilbene-type carboxylic acids 1 bearing EWGs under the influence of urea-type chiral bifunctional sulfide catalysts (S)-4. The target chiral phthalide products 2 were obtained with moderate to good levels of enantioselectivity. The bifunctional design of catalysts (S)-4 with a urea moiety was essential in obtaining good levels of regio- and enantioselectivity for the proposed 5-exo bromolactonization.

(12) General Procedure for Asymmetric Bromolactonizations

To a solution of substrate 1 (0.10 mmol) and catalyst (S)-4d (10 mol %, 0.010 mmol) in CH2Cl2 (2.0 mL) was cooled to 0 °C. After stirring for 10 min at 0 °C, N-bromosuccinimide (NBS) (0.12 mmol) was added to the cooled reaction solution. The reaction mixture was stirred for 24 h at 0 °C. After 24 h, the reaction mixture was quenched with saturated aqueous Na2SO3 (4.0 mL) at 0 °C and stirred for 10 min at 0 °C. The quenched reaction mixture was diluted with CH2Cl2 (2 mL) and H2O (2 mL), and warmed to room temperature. The organic materials were extracted with CHCl3 for three times (5.0 mL × 3). The combined extracts were dried over Na2SO4 and concentrated. [The 1H NMR analysis of the crude reaction mixture was performed at this stage to determine the enantioselectivity of bromolactonization products.] The residue was purified by flash column chromatography on silica gel (hexane/ethyl acetate as eluent) to give product 2. The enantioselectivity of the product 2 was determined by HPLC analysis on a chiral stationary phase.
